Began with imports to make sure assignment ran smoothly.

Created an empty list that I would later put names into, along with a counter of the total names, starting it at zero.

First thing I put in the try was the scanner. Then read the name from the first lines and the first double, looping around to each student until there was no longer a next line for student name.

Used the same catch as we have been in class, looking for file not found expection.

Included an if statement, checking each GPA to see if it was greater than 3.5. If it was the name associated was added to the initial list. Then printing the list along with the number for how many times the while loop was ran to see how many names were in the list.
