I began by importing the scanner that will be needed when inputting answers for the game. Then like always, did public static void main. Before anything else, assigned a name to the scanner so it could be used later on, calling it "sc". I also started out by making the score 0, as a base. The first thing that is printed to the user is a welcome message, letting them know there is a game to be played. Then it begins with the first question. Since the answer is an integer, the "if" statement checks if they are equal, and if they are, the program adds one to the score and prints a message telling them they are correct and what their new score is. If the answer given is not correct, it tells them they are wrong and that their score remains the same. After repeating the same process three times, it prints a final message telling the user what their final score is.
